

Importing Data Sets in R

Working with data provided by R packages is a great way to learn the tools of data science, but at some point you want to stop learning and start working with your own data.

We will explore how to import the following common types of files into R.

1. Excel Files
2. csv files
3. SPSS files
4. STATA files

Each of the above files has an equivalent package in R to import the respective file.

csv files

CSV files are the most commonly used data files. To import this we can use the two options namely:

- `read.csv()`
- `read_csv()` from the `readr` package

You have to specify the file path if you are not working inside a R Project.

Example is as shown:

```
mydata <- read.csv("/path to data file/data.csv")
```

The alternative form is given as:

```
library(readr)
mydata <- read_csv("/path to data file/data.csv")
```

Excel files

R has the capability of importing excel files using the readxl package

```
library(readxl)

mydata <- read_excel("/path to data file/data.xlsx")
```

You can also specify the sheet name you want to import the specific data from

```
library(readxl)

mydata <- read_excel("/path to data file/data.xlsx, sheet = sheetname")
```

SPSS files

SPSS files can be imported via the haven or foreign packages in R.

The extension of SPSS files is .sav

```
library(haven)

mydata <- read_sav("/path to data file/data.sav")
```

STATA files

STATA files can be imported via the haven or foreign packages in R.

The extension of STATA files is .dta

```
library(haven)

mydata <- read_dta("/path to data file/data.dta")
```

Probability Distributions

Probability measures how likely it is for an event to occur on a scale from 0 to 1.

A probability distribution describes how a random variable is distributed; it tells us which values a random variable is most likely to take on and which values are less likely.
